# Foundations of Artificial Intelligence 13. Knowledge Representation: Modeling with Logic Concepts, Actions, Time, & All the Rest

Wolfram Burgard, Bernhard Nebel, and Martin Riedmiller

Albert-Ludwigs-Universität Freiburg

August 2, 2011

### Contents

- 1 Knowledge Representation and Reasoning
- Concepts & Description Logics
- 3 Logical Agents for the WUMPUS World
- Situation Calculus
- The Frame Problem
- Time Intervals and Their Description

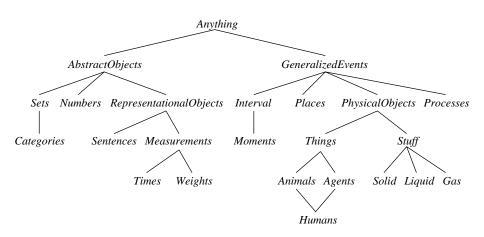

# Knowledge Representation and Reasoning

- Often, our agents need knowledge before they can start to act intelligently
- They then also need some reasoning component to exploit the knowledge they have
- Examples:
  - Knowledge about the important concepts in a domain
  - Knowledge about actions one can perform in a domain
  - Knowledge about temporal relationships between events
  - Knowledge about the world and how properties are related to actions

# Categories and Objects

- We need to describe the objects in our world using categories
- Necessary to establish a common category system for different applications (in particular on the web)
- There are a number of quite general categories everybody and every application uses

# The Upper Ontology: A General Category Hierarchy

# **Description Logics**

- How to describe more specialized things?
- Use definitions and/or necessary conditions referring to other already defined concepts:

A parent is a human with at least one child.

• More complex description:

A proud-grandmother is a human, which is female with at least two children that are in turn parents whose children are all doctors.

# Reasoning Services in Description Logics

#### Typical questions of interest:

- Subsumption: Determine whether one description is more general than (subsumes) the other
- Classification: Create a subsumption hierarchy
- Satisfiability: Is a description satisfiable?
- Instance relationship: Is a given object instance of a concept description?
- Instance retrieval: Retrieve all objects for a given concept description

# Special Properties of Description Logics

- Semantics of description logics (DLs) can be given using ordinary PL1
- Alternatively, DLs can be considered as modal logics
- Reasoning for most DLs is much more efficient than for PL1
- Nowadays, W3C standards such as OWL (formerly DAML+OIL) are based on description logics

# Logic-Based Agents That Act

```
 \begin{array}{c} \textbf{function KB-AGENT}(\textit{percept}) \ \textbf{returns} \ \text{an} \ \textit{action} \\ \textbf{persistent} \colon \textit{KB}, \ \text{a knowledge base} \\ \textit{t}, \ \text{a counter}, \ \text{initially 0, indicating time} \\ \end{array}
```

```
Tell(KB, Make-Percept-Sentence(percept, t)) action \leftarrow Ask(KB, Make-Action-Query(t)) Tell(KB, Make-Action-Sentence(action, t)) t \leftarrow t+1 return action
```

Query (Make-Action-Query):  $\exists x Action(x, t)$ 

A variable assignment for x in the WUMPUS world example should give the following answers: turn(right), turn(left), forward, shoot, grab, release, climb.

# Reflex Agents

... only react to percepts.

Example of a percept statement (at time 5):

$$Percept(stench, breeze, glitter, none, none, 5)$$

1. 
$$\forall b, g, u, c, t[Percept(stench, b, g, u, c, t) \Rightarrow Stench(t)]$$
  
 $\forall s, g, u, c, t[Percept(s, breeze, g, u, c, t) \Rightarrow Breeze(t)]$   
 $\forall s, b, g, u, c, t[Percept(s, b, glitter, u, c, t) \Rightarrow AtGold(t)]$ 

. . .

2. Step: Choice of action

$$\forall t[AtGold(t) \Rightarrow Action(grab, t)]$$

Note: Our reflex agent does not know when it should climb out of the cave and cannot avoid an infinite loop.

# Model-Based Agents

- ... have an internal model
- of all basic aspects of their environment,
- of the executability and effects of their actions,
- of further basic laws of the world, and
- of their own goals.

Important aspect: How does the world change?

→ Situation calculus: (McCarthy, 63).

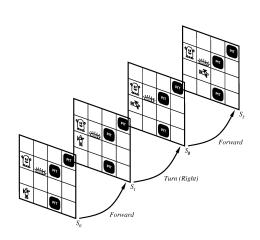

### Situation Calculus

- A way to describe dynamic worlds with PL1.
- States are represented by terms.
- The world is in state s and can only be altered through the execution of an action: do(a,s) is the resulting situation, if a is executed.
- Actions have preconditions and are described by their effects.
- Relations whose truth value changes over time are called fluents. Represented through a predicate with two arguments: the fluent and a state term. For example, At(x,s) means, that in situation s, the agent is at position s. Holding(y,s) means that in situation s, the agent holds object s.
- Atemporal or eternal predicates, e.g., Portable(gold).

# Example: WUMPUS-World

# Let $s_0$ be the initial situation and

$$s_1 = do(forward, s_0)$$
  
 $s_2 = do(turn(right), s_1)$   
 $s_3 = do(forward, s_2)$ 

13 / 25

# Description of Actions

Preconditions: In order to pick something up, it must be both present and portable:

$$\forall x, s[Poss(grab(x), s) \Leftrightarrow Present(x, s) \land Portable(x)]$$

In the WUMPUS-World:

$$Portable(gold), \forall s[AtGold(s) \Rightarrow Present(gold, s)]$$

Positive effect axiom:

$$\forall x, s[Poss(grab(x), s) \Rightarrow Holding(x, do(grab(x), s))]$$

Negative effect axiom:

$$\forall x, s \neg Holding(x, do(release(x), s))$$

### The Frame Problem

We had:  $Holding(gold, s_0)$ .

Following situation:  $\neg Holding(gold, do(release(gold), s_0))$ ?

We had:  $\neg Holding(gold, s_0)$ .

Following situation:  $\neg Holding(gold, do(turn(right), s_0))$ ?

- We must also specify which fluents remain unchanged!
- The frame problem: Specification of the properties that *do not* change as a result of an action.
- → Frame axioms must also be specified.

### Number of Frame Axioms

$$\forall a, x, s[Holding(x, s) \land (a \neq release(x)) \Rightarrow Holding(x, do(a, s))]$$
  
$$\forall a, x, s[\neg Holding(x, s) \land \{(a \neq grab(x)) \lor \neg Poss(grab(x), s)\}$$
  
$$\Rightarrow \neg Holding(x, do(a, s))]$$

Can be very expensive in some situations, since  $O(|F| \times |A|)$  axioms must be specified, F being the set of fluents and A being the set of actions.

### Successor-State Axioms

A more elegant way to solve the frame problem is to fully describe the successor situation:

true after action

 $\Leftrightarrow$  [ action made it true or, already true and the action did not falsify it ]

Example for grab:

$$\forall a, x, s[Holding(x, do(a, s)) \\ \Leftrightarrow \{(a = grab(x) \land Poss(a, s)) \lor (Holding(x, s) \land a \neq release(x))\}]$$

Can also be automatically compiled by only giving the effect axioms (and then applying *explanation closure*). Here we suppose that only certain effects can appear.

### Limits of this Version of Situation Calculus

- No explicit time. We cannot discuss how long an action will require, if it is executed.
- Only one agent. In principle, however, several agents can be modeled.
- No parallel execution of actions.
- Discrete situations. No continuous actions, such as moving an object from A to B.
- Closed world. Only the agent changes the situation.
- Determinism. Actions are always executed with absolute certainty.
- → Nonetheless, sufficient for many situations.

# Qualitative Descriptions of Temporal Relationships

We can describe the temporal occurrence of event/actions:

- absolute by using a date/time system
- relative with respect to other event occurrences
- quantitatively, using time measurements (5 secs)
- qualitatively, using comparisons (before/overlaps)

### Allen's Interval Calculus

- Allen proposed a calculus about relative order of time intervals
- Allows us to describe, e.g.,
  - Interval I occurs before interval J
  - Interval J occurs before interval K
- and to conclude
  - Interval I occurs before interval K
- ightarrow 13 jointly exhaustive and pair-wise disjoint relations between intervals

### Allen's 13 Interval Relation

$$\stackrel{I}{\longleftarrow} \stackrel{J}{\longleftarrow}$$

I < J, J > Ibefore/after

 $I s J, J s^{-1} I$ starts

 $I m J, J m^{-1} I$ meets

$$I \longrightarrow J$$

 $I d J, J d^{-1} I$ during

$$I = J$$

 $I \circ J, \ J \circ^{-1} I$ overlaps

 $I f J, J f^{-1} I$ finishes

# **Examples**

 Using Allen's relation system one can describe temporal configurations as follows:

$$X < Y, Y \circ Z, Z > X$$

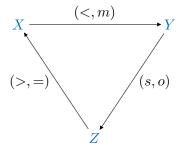

• One can also use disjunctions (unions) of temporal relations:

# Reasoning in Allen's Relations System

How do we reason in Allen's system

- Checking whether a set of formulae is satisfiable
- Checking whether a temporal formula follows logically
- ightarrow Use a constraint propagation technique for CSPs with infinite domains (3-consistency), based on *composing relations*

# Constraint Propagation

$$X < Y s Z = X Z$$
  
 $X < Y o Z = X Z$   
 $X m Y s Z = X Z$   
 $X m Y o Z = X Z$ 

Do that for every triple until nothing changes anymore, then CSP is 3-consistent

# Concluding Remarks: Use of Logical Formalisms

- In many (but not all) cases, full inference in PL1 is simply too slow (and therefore too unreliable).
- Often, special (logic-based) representational formalisms are designed for specific applications, for which specific inference procedures can be used. Examples:
  - Description logics for representing conceptual knowledge.
  - James Allen's time interval calculus for representing qualitative temporal knowledge.
  - Planning: Instead of situation calculus, this is a specialized calculus (STRIPS) that allows us to address the frame problem.
