

Robot Mapping

Hierarchical Pose-Graphs for Online Mapping

**Gian Diego Tipaldi, Luciano Spinello,
Wolfram Burgard**

Graph-Based SLAM (Chap. 15)

- Constraints connect the poses of the robot while it is moving
- Constraints are inherently uncertain

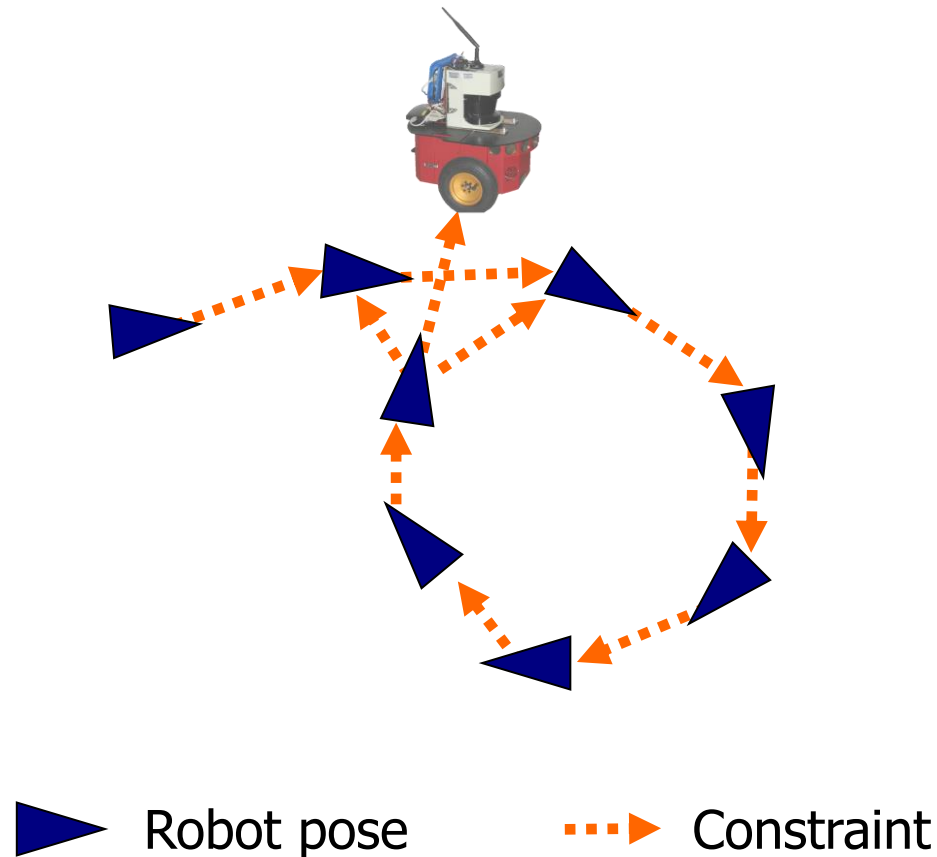

▶ Robot pose

⋯▶ Constraint

Graph-Based SLAM (Chap. 15)

- Observing previously seen areas generates constraints between non-successive poses

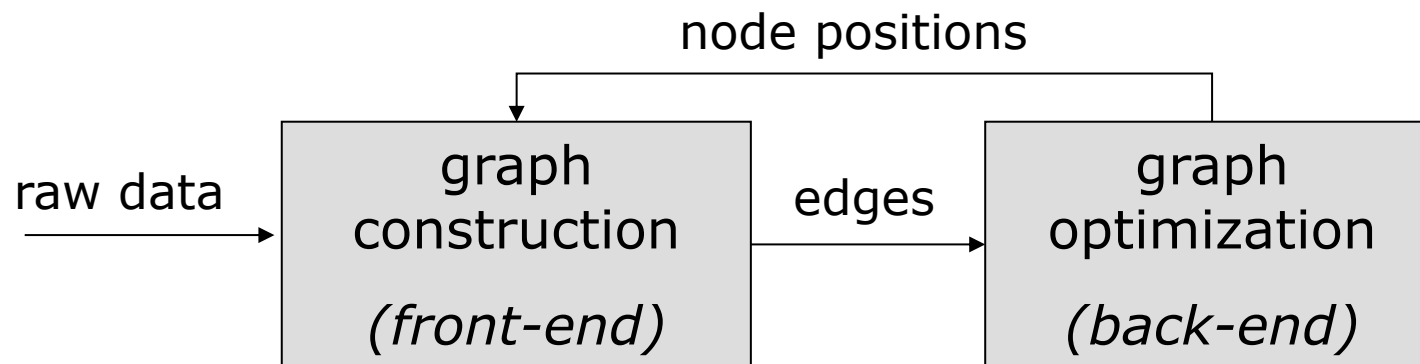

Graph-Based SLAM (Chap. 15)

- Use a **graph** to represent the problem
- Every **node** in the graph corresponds to a pose of the robot during mapping
- Every **edge** between two nodes corresponds to a spatial constraint between them
- **Graph-Based SLAM:** Build the graph and find a node configuration that minimize the error introduced by the constraints

Front-End and Back-End

- Front-end extracts constraints from the sensor data (data association!)
- Back-end optimizes the pose-graph to reduce the error introduced by the constraints

➔ Intermediate solutions are needed to make good data associations

Hierarchical Pose-Graph

bottom layer
(input data)

first layer

second layer

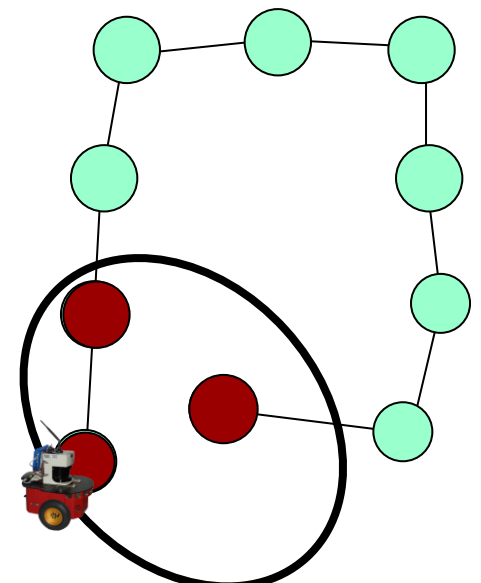

top layer

“There is no need to optimize the whole graph when a new observation is obtained”

Motivation

- SLAM front-end seeks for loop-closures
- Requires to compare observations to all previously obtained ones
- In practice, limit search to areas in which the robot is likely to be
- This requires to know **in which parts of the graph to search for data associations**

Hierarchical Approach

- **Insight:** to find loop closing points, one does not need the perfect global map
- **Idea:** correct only the core structure of the scene, not the overall graph
- The hierarchical pose-graph is a sparse approximation of the original problem
- It exploits the facts that in SLAM
 - Robot moved through the scene and it not “teleported” to locations
 - Sensors have a limited range

Key Idea of the Hierarchy

- Input is the dense graph

Key Idea of the Hierarchy

- Input is the dense graph
- Group the nodes of the graph based on their local connectivity

Key Idea of the Hierarchy

- Input is the dense graph
- Group the nodes of the graph based on their local connectivity
- For each group, select one node as a "representative"

Key Idea of the Hierarchy

- The representatives are the nodes in a new sparsified graph (upper level)

Key Idea of the Hierarchy

- The representatives are the nodes in a new sparsified graph (upper level)
- Edges of the sparse graph are determined by the connectivity of the groups of nodes
- The parameters of the sparse edges are estimated via local optimization

Key Idea of the Hierarchy

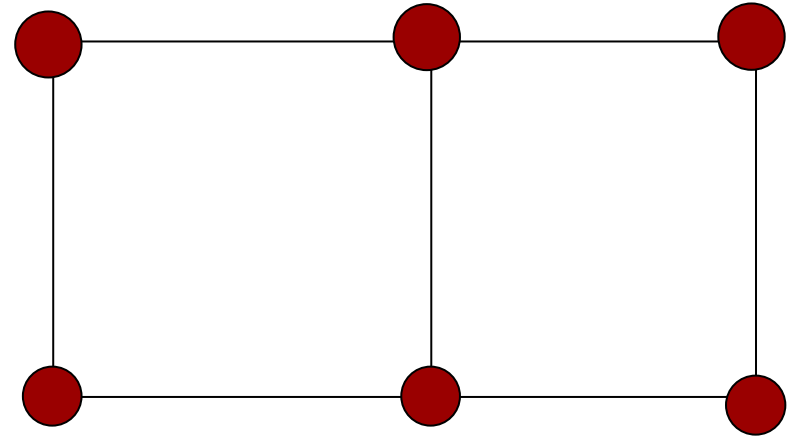

- The representatives are the nodes in a new sparsified graph (upper level)
- Edges of the sparse graph are determined by the connectivity of the groups of nodes
- The parameters of the sparse edges are estimated via local optimization

Process is
repeated
recursively

Key Idea of the Hierarchy

- Only the upper level of the hierarchy is optimized completely

Key Idea of the Hierarchy

- Only the upper level of the hierarchy is optimized completely
- The changes are propagated to the bottom levels only close to the current robot position
- Only this part of the graph is relevant for finding constraints

Construction of the Hierarchy

- When and how to generate a new group?
 - A (simple) distance-based decision
 - The first node of a new group is the representative
- When to propagate information downwards?
 - Only when there are inconsistencies
- How to construct an edge in the sparsified graph?
 - Next slides
- How to propagate information downwards?
 - Next slides

Determining Edge Parameters

- Given two connected groups
- How to compute a virtual observation \mathbf{Z} and the information matrix Ω for the new edge?

Determining Edge Parameters

- Optimize the two subgroups independently from the rest

Determining Edge Parameters

- Optimize the two subgroups independently from the rest
- The observation is the relative transformation between the two representatives

Determining Edge Parameters

- Optimize the two subgroups independently from the rest
- The observation is the relative transformation between the two representatives
- The information matrix is computed from the diagonal block of the matrix \mathbf{H}

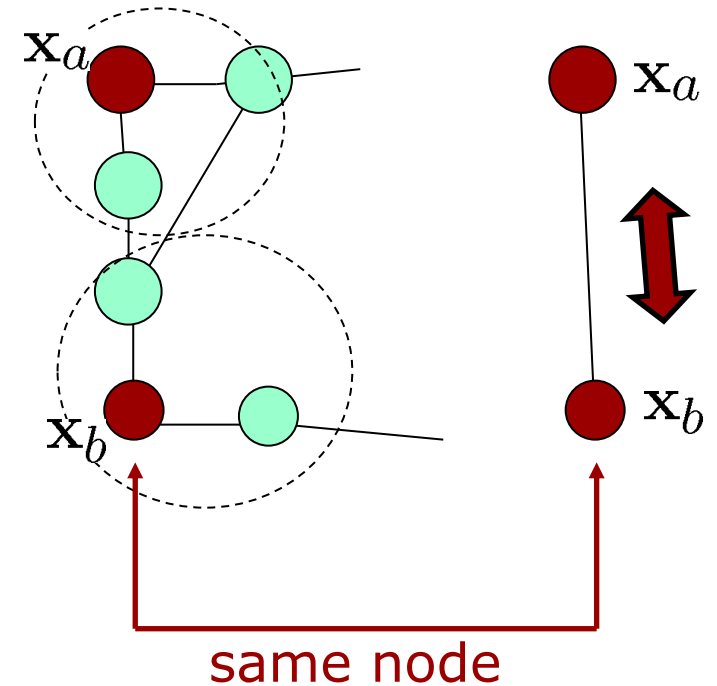

Inverse of the $[b,b]$
block of \mathbf{H}^{-1}

$$\Omega_{ab} = (\mathbf{H}_{[b,b]}^{-1})^{-1}$$

Propagating Information Downwards

- All representatives are nodes from the lower (bottom) level

Propagating Information Downwards

- All representatives are nodes from the lower (bottom) level
- Information is propagated downwards by transforming the group at the lower level using a rigid body transformation

Propagating Information Downwards

- All representatives are nodes from the lower (bottom) level
- Information is propagated downwards by transforming the group at the lower level using a rigid body transformation
- Only if the lower level becomes inconsistent, optimize at the lower level

For the Best Possible Map...

- Run the optimization on the lowest level (at the end)
- For offline processing with all constraints, the hierarchy helps convergence faster in case of large errors
- In this case, one pass up the tree (to construct the edges) followed by one pass down the tree is sufficient

Stanford Garage

- Parking garage at Stanford University
- Nested loops, trajectory of $\sim 7,000\text{m}$

Stanford Garage Result

- Parking garage at Stanford University
- Nested loops, trajectory of $\sim 7,000\text{m}$

Consistency

- How well does the top level in the hierarchy represent the original input?

Consistency

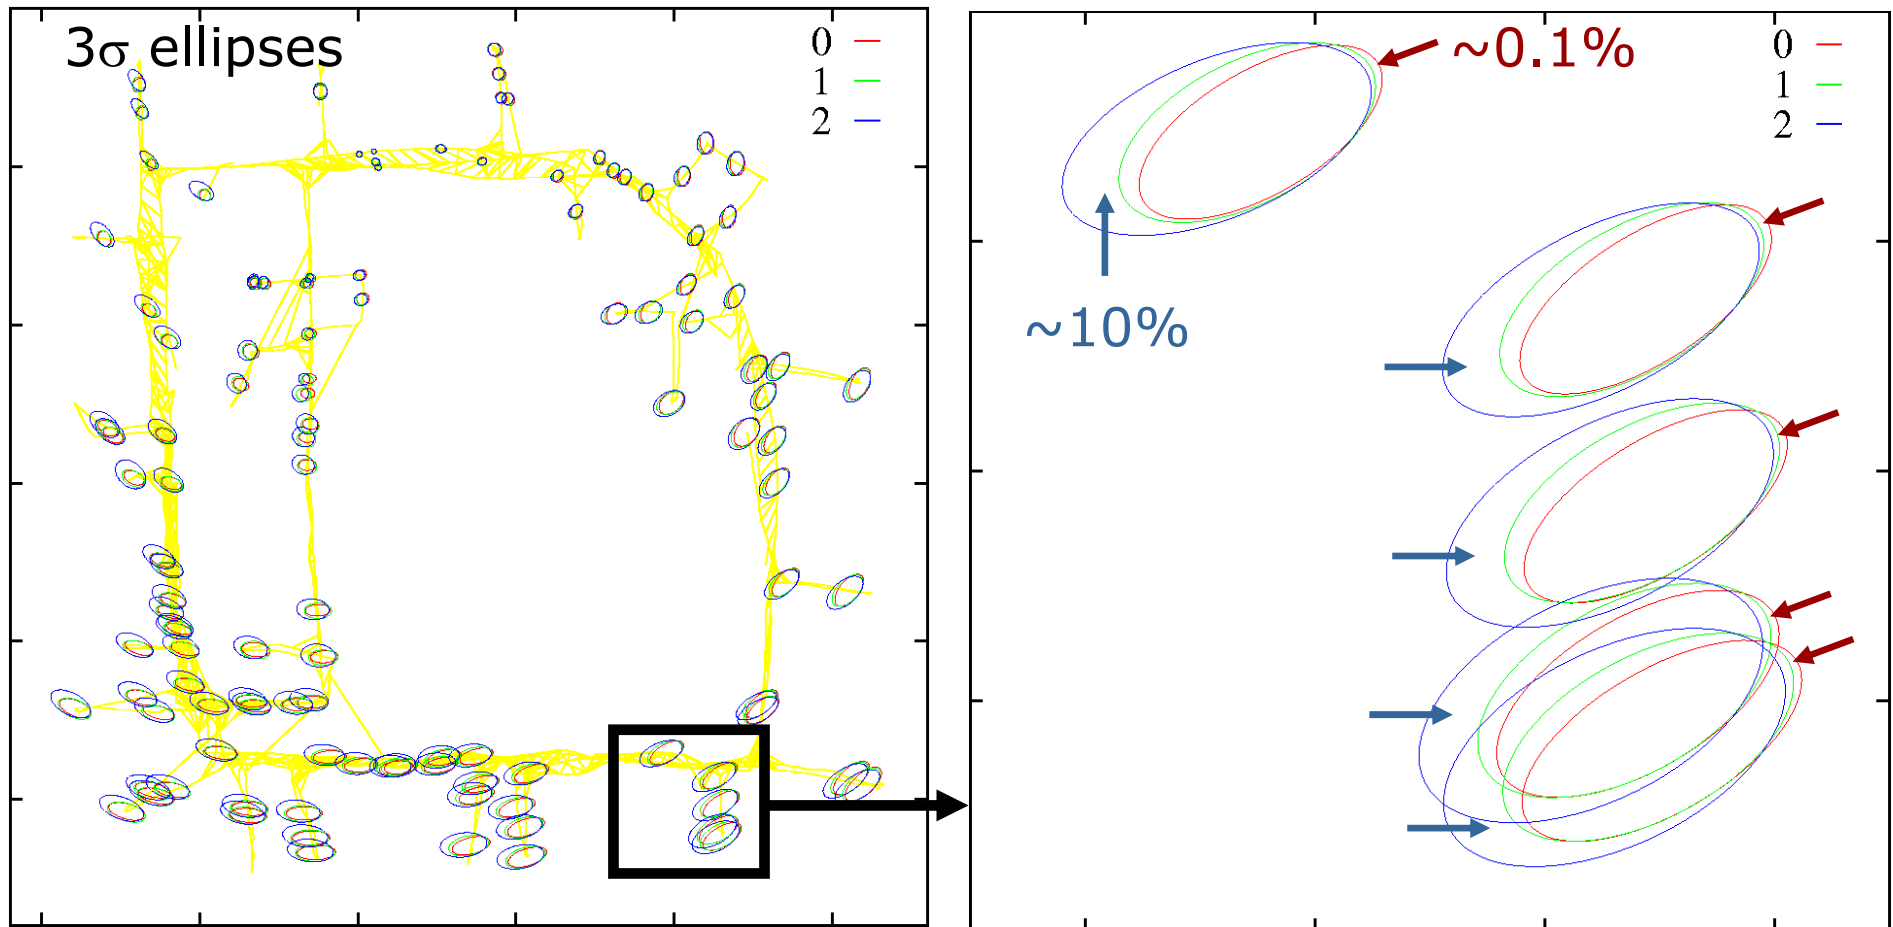

- How well does the top level in the hierarchy represent the original input?
- Probability mass of the marginal distribution in the highest level vs. the one of the true estimate (original problem, lowest level)

	Prob. mass not covered	Prob. mass outside
Intel	0.10%	10.18%
W-10000	2.53%	24.05%
Stanford	0.01%	7.88%
Sphere	2.75%	10.21%

low risk of becoming overly confident

one does not ignore too much information

Consistency

- **Red**: overly confident ($\sim 0.1\%$ prob. mass)
- **Blue**: under confident ($\sim 10\%$ prob. mass)

Conclusions

- Hierarchical pose-graph to estimate the structure to support efficient data association
- Designed for online mapping (interplay between optimization and data association)
- Higher level represent simplified problem

Slide Information

- These slides have been created by Cyrill Stachniss as part of the robot mapping course taught in 2012/13 and 2013/14. I created this set of slides partially extending existing material of Giorgio Grisetti and myself.
- I tried to acknowledge all people that contributed image or video material. In case I missed something, please let me know. If you adapt this course material, please make sure you keep the acknowledgements.
- Feel free to use and change the slides. If you use them, I would appreciate an acknowledgement as well. To satisfy my own curiosity, I appreciate a short email notice in case you use the material in your course.
- My video recordings are available through YouTube:
